QUESTION: Name and explain two monitoring performance tools of a computer

Monitoring performance tools are tools that help diagnose performance issues, manage resources and optimize system performance viewing real-time activities, performance tools include the following;

Task Manager (windows): These are utility programs and tools that associates with in built tools that monitor system resources and run processes since they provide a real-time overview of a system performance, that displays Central Processing Unit (CPU), memory, disk, network usage, resource-intensive process identification and process management to identify resource applications so that users can monitor running processes, system performance graphs enhance system security and make it easy to trouble shoot issues. Types of such managers include built-in task managers which include activity (Mac) (command+options+Esc) and system (Linux) monitor for real-time monitoring, resource leak detection performance optimization and third-party task managers which include process explorer and system explorer windows for system crash prevention, automated tasks, system monitoring and user-friendly interface. Task manager shortcuts include ctrl+shift+Esc.

Process Explorer (windows): It is also known as activity monitor a freeware task manager and system monitor for windows this monitors system processes and resources. It shows processes, Central Processing Unit (CPU), memory usage, energy consumption, disk activity helping users identify which applications are consuming resources and can assist in managing system performance effectively. Process Explorer works as an advanced process management utility that picks up where Task manager leaves off it will show you detailed information about a process including its icon, command-line, user account, security attributes, and more whereas the information displayed in the bottom window which can close depends on the mode .it has keys like ctrl+f for search, ctrl +E for end processes, ctrl+ R for refresh and others for comprehensive process management.

In conclusion, the two monitoring performance tools discussed do provide valuable insights into a computer performance and both optimize resource allocation.
